

Fall - 2022 (Data Structure)

Q1) # Write a Case where using arrays provides advantages instead of linked lists.

Ans:

(i) Random Access: Arrays allow for direct access to elements using their index. Accessing an element in array takes $O(1)$ time complexity, whereas linked list require traversing from head node to reach specific element cause $O(n)$.

(ii) Memory Efficiency: Array is more memory efficient as it doesn't require extra memory for storing pointers to the next node.

(iii) Cache Locality: accessing element in array is faster due to reduced cache misses.

(iv) Arrays are simpler. They have fixed size making it easy to allocate memory management.

- ⑥ If Given a linked list and 2 integers m and v write Pseudo code with
- ① First insert a node with the item value m at the beginning.
 - ② Then delete last v node from L.
- Algorithm
- Function insertDelete(head, m, v)
- ① Create a new node with value m .
 - ② Set the next pointer of the new node to the current head of the LL.
 - ③ Update the head with new node.
 - ④ Count = 0
 - ⑤ If the count is less than v continue to next node.
- ⑦ If count is v , set the next pointer previous node to None.
- ⑧ Increment count
- Simulation
- ① initial - 1, 3, 5, 7
- $m=0, v=2$
- 2) Insert $m=0$ at begin.: 0, 1, 3, 5, 7
- 3) Delete last v node. : 0, 1, 3, 5, 7

- Q) What are the advantages where using Linked List
- Provides advantages instead of array
- Ans: ~~simply not suited for~~
- (1) Dynamic size: L.L can easily grow or shrink during runtime. They do not require predefining size like array.
 - (2) Efficient insertion Deletion: insertion and deletion require $O(1)$ time complexity in L.L where array require $O(n)$.
 - (3) No waste memory: L.L only allocate memory for elements when needed. array often have unused allocated memory due to its static nature.

4) Ease of implementation; when dealing with operations that require frequent resizing.

LL is better than Dynamic Array.

5) inserting, deleting at the beginning or end of a linked list can be done in O(1) time which is more efficient, compared to arrays where this required shifting all the elements. But O(n) space is needed.

- B) # 2 integers m and k. write code,
- ① First insert a node with the item value m at the end of the list.
 - ② Then delete k nodes from L.L.

ii) Queue type of Data Structure will be appropriate for implementing this traversal algorithm. Because BFS uses a queue to maintain the order of exploration, when you visit a vertex you enqueue it, adjacent unvisited vertices. The vertices are enqueued in the order they were enqueued, ensuring that closer vertices are visited before farther one.

① Queue follows first in first out principle. The friends who informed first will be discovered first.

Reversing Us

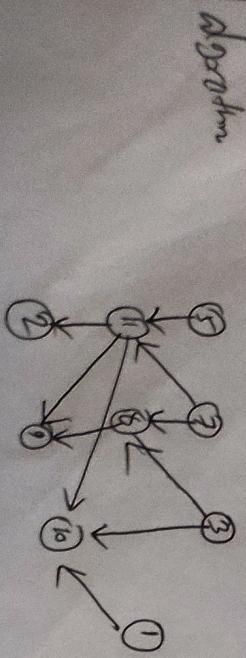

3) It starts from a vertex and then wants to visit every vertex from the list till it has no unvisited adjacent vertex. After that it explores other vertex back and so far. What is the most suitable graph traversal algorithm should be from the same vertex? From the starting vertex, it has to go as deep as possible before backtracking. In this case, DFS would allow the person to go as deep as possible before coming back from the starting vertex. From the starting vertex, it has to go as deep as possible before coming back from the starting vertex.

Ans:

The most suitable graph traversal is Depth first search (DFS). DFS explores as far as possible along each branch before backtracking. In this case, DFS would allow the person to go as deep as possible before coming back from the starting vertex. From the starting vertex, it has to go as deep as possible before coming back from the starting vertex.

- Q) According to your answer show the traversing skill on the following graph. You have the freedom to choose any vertex as the starting vertex to choose and explore.

- i) What type of data structure (stack/queue) will be appropriate for implementing this traversal algorithm?

ii) The Suitable Graph is DFS. So the type of Data Structure will be used is stack.

① Stack is used to keep track of the vertices to be visited. also can use recursion implicitly or stack explicitly.

② When reach a vertex, push it to stack then explore as deep as possible recursively visiting adjacent unvisited vertices.

③ When there are no more unvisited adjacent vertices, you back track by popping vertex from the stack to explore other branches,

Stack is appropriate because it allows for backtracking efficiently.

Elements are added to the stack when exploring new vertices and removed from stack during exploration path forming correctly

Fall-22 - Data Structure

- Q) a) The worst time complexity to delete an array element is $O(n)$, justify this statement.
- Sol: The statement is justified because in the worst case scenario an element from an array you might have to shift all the subsequent elements to fill the gap left by deleted element. The operation takes linear time proportional to the number of elements in the array (n) leading to time complexity $O(n)$.

- Qa) Why recursion important in Data Structure, write some example of it.
- b) Recursion is important for solving problems with repetitive structure. If follows the divide and conquer strategy, recursive code is often more readable and descent.
